Dynamic Asset-Allocation and Consumption

- The broad topic is Investment Management
- Applies to Corporations as well as Individuals
- The two considerations are:
 - How to allocate money across assets in one's investment portfolio
 - How much to consume for one's needs/operations/pleasures
- We consider the dynamic version of these dual considerations
- Asset-Allocation and Consumption decisions at each time step
- Asset-Allocation decisions typically deal with Risk-Reward tradeoffs
- Consumption decisions are about spending now or later
- Objective: Horizon-Aggregated Expected Utility of Consumption

Let's consider the simple example of Personal Finance

- Broadly speaking, Personal Finance involves the following aspects:
 - Receiving Money: Salary, Bonus, Rental income, Asset Liquidation etc.
 - Consuming Money: Food, Clothes, Rent/Mortgage, Car, Vacations etc.
 - Investing Money: Savings account, Stocks, Real-estate, Gold etc.
- Goal: Maximize lifetime-aggregated Expected Utility of Consumption
- This can be modeled as a Markov Decision Process
- *State*: Age, Asset Holdings, Asset Valuation, Career situation etc.
- *Action*: Changes in Asset Holdings, Optional Consumption
- *Reward*: Utility of Consumption of Money
- *Model*: Career uncertainties, Asset market uncertainties

Merton's Frictionless Continuous-Time Formulation

- Assume: Current wealth is $W_0 > 0$, and you'll live for T more years
- You can invest in (allocate to) n risky assets and a riskless asset
- Each risky asset has known normal distribution of returns
- Allowed to long or short any fractional quantities of assets
- Trading in continuous time $0 \leq t < T$, with no transaction costs
- You can consume any fractional amount of wealth at any time
- Dynamic Decision: Optimal Allocation and Consumption at each time
- To maximize lifetime-aggregated Expected Utility of Consumption
- Consumption Utility assumed to have Constant Relative Risk-Aversion

Problem Notation

For simplicity, we state and solve the problem for 1 risky asset but the solution generalizes easily to n risky assets.

- Riskless asset: $dR_t = r \cdot R_t \cdot dt$
- Risky asset: $dS_t = \mu \cdot S_t \cdot dt + \sigma \cdot S_t \cdot dz_t$ (i.e. Geometric Brownian)
- $\mu > r > 0, \sigma > 0$ (for n assets, we work with a covariance matrix)
- Wealth at time t is denoted by $W_t > 0$
- Fraction of wealth allocated to risky asset denoted by $\pi(t, W_t)$
- Fraction of wealth in riskless asset will then be $1 - \pi(t, W_t)$
- Wealth consumption per unit time denoted by $c(t, W_t) \geq 0$
- Utility of Consumption function $U(x) = \frac{x^{1-\gamma}}{1-\gamma}$ for $0 < \gamma \neq 1$
- Utility of Consumption function $U(x) = \log(x)$ for $\gamma = 1$
- $\gamma = (\text{Constant}) \text{ Relative Risk-Aversion } \frac{-x \cdot U''(x)}{U'(x)}$

Formal Problem Statement

- We write π_t, c_t instead of $\pi(t, W_t), c(t, W_t)$ to lighten notation
- Balance constraint implies the following process for Wealth W_t

$$dW_t = ((\pi_t \cdot (\mu - r) + r) \cdot W_t - c_t) \cdot dt + \pi_t \cdot \sigma \cdot W_t \cdot dz_t$$

- At any time t , determine optimal $[\pi(t, W_t), c(t, W_t)]$ to maximize:

$$\mathbb{E}\left[\int_t^T \frac{e^{-\rho(s-t)} \cdot c_s^{1-\gamma}}{1-\gamma} \cdot ds + \frac{e^{-\rho(T-t)} \cdot B(T) \cdot W_T^{1-\gamma}}{1-\gamma} \mid W_t\right]$$

- where $\rho \geq 0$ is the utility discount rate, $B(T)$ is the bequest function
- We can solve this problem for arbitrary bequest $B(T)$ but for simplicity, will consider $B(T) = \epsilon^\gamma$ where $0 < \epsilon \ll 1$, meaning “no bequest” (we need this ϵ -formulation for technical reasons).
- We will solve this problem for $\gamma \neq 1$ ($\gamma = 1$ is easier, hence omitted)

Continuous-Time Stochastic Control

- Think of this as a continuous-time Stochastic Control problem
- The *State* at time t is (t, W_t)
- The *Action* at time t is $[\pi_t, c_t]$
- The *Reward* per unit time at time t is $U(c_t) = \frac{c_t^{1-\gamma}}{1-\gamma}$
- The *Return* at time t is the accumulated discounted *Reward*:

$$\int_t^T e^{-\rho(s-t)} \cdot \frac{c_s^{1-\gamma}}{1-\gamma} \cdot ds$$

- Find *Policy* : $(t, W_t) \rightarrow [\pi_t, c_t]$ that maximizes the *Expected Return*
- Note: $c_t \geq 0$, but π_t is unconstrained

Optimal Value Function

- Value Function for a *State* (under a given policy) is the *Expected Return* from the *State* (when following the given policy)
- We focus on the Optimal Value Function $V^*(t, W_t)$

$$V^*(t, W_t) = \max_{\pi, c} \mathbb{E}_t \left[\int_t^T \frac{e^{-\rho(s-t)} \cdot c_s^{1-\gamma}}{1-\gamma} \cdot ds + \frac{e^{-\rho(T-t)} \cdot \epsilon^\gamma \cdot W_T^{1-\gamma}}{1-\gamma} \right]$$

- $V^*(t, W_t)$ satisfies a simple recursive formulation for $0 \leq t < t_1 < T$

$$V^*(t, W_t) = \max_{\pi, c} \mathbb{E}_t \left[\int_t^{t_1} \frac{e^{-\rho(s-t)} \cdot c_s^{1-\gamma}}{1-\gamma} \cdot ds + e^{-\rho(t_1-t)} \cdot V^*(t_1, W_{t_1}) \right]$$

$$\Rightarrow e^{-\rho t} \cdot V^*(t, W_t) = \max_{\pi, c} \mathbb{E}_t \left[\int_t^{t_1} \frac{e^{-\rho s} \cdot c_s^{1-\gamma}}{1-\gamma} \cdot ds + e^{-\rho t_1} \cdot V^*(t_1, W_{t_1}) \right]$$

HJB Equation for Optimal Value Function

Rewriting in stochastic differential form, we have the HJB formulation

$$\max_{\pi_t, c_t} \mathbb{E}_t \left[d(e^{-\rho t} \cdot V^*(t, W_t)) + \frac{e^{-\rho t} \cdot c_t^{1-\gamma}}{1-\gamma} \cdot dt \right] = 0$$

$$\Rightarrow \max_{\pi_t, c_t} \mathbb{E}_t \left[dV^*(t, W_t) + \frac{c_t^{1-\gamma}}{1-\gamma} \cdot dt \right] = \rho \cdot V^*(t, W_t) \cdot dt$$

Use Ito's Lemma on dV^* , remove the dz_t term since it's a martingale, and divide throughout by dt to produce the HJB Equation in PDE form:

$$\begin{aligned} \max_{\pi_t, c_t} \left[\frac{\partial V^*}{\partial t} + \frac{\partial V^*}{\partial W} ((\pi_t(\mu - r) + r)W_t - c_t) + \frac{\partial^2 V^*}{\partial W^2} \cdot \frac{\pi_t^2 \sigma^2 W_t^2}{2} + \frac{c_t^{1-\gamma}}{1-\gamma} \right] \\ = \rho \cdot V^*(t, W_t) \end{aligned}$$

Let us write the above equation more succinctly as:

$$\max_{\pi_t, c_t} \Phi(t, W_t; \pi_t, c_t) = \rho \cdot V^*(t, W_t)$$

Note: we are working with the constraints $W_t > 0, c_t \geq 0$ for $0 \leq t < T$

Optimal Allocation and Consumption

Find optimal π_t^*, c_t^* by taking partial derivatives of $\Phi(t, W_t; \pi_t, c_t)$ with respect to π_t and c_t , and equate to 0 (first-order conditions for Φ).

- Partial derivative of Φ with respect to π_t :

$$(\mu - r) \cdot \frac{\partial V^*}{\partial W_t} + \frac{\partial^2 V^*}{\partial W_t^2} \cdot \pi_t \cdot \sigma^2 \cdot W_t = 0$$

$$\Rightarrow \pi_t^* = \frac{-\frac{\partial V^*}{\partial W_t} \cdot (\mu - r)}{\frac{\partial^2 V^*}{\partial W_t^2} \cdot \sigma^2 \cdot W_t}$$

- Partial derivative of Φ with respect to c_t :

$$-\frac{\partial V^*}{\partial W_t} + (c_t^*)^{-\gamma} = 0$$

$$\Rightarrow c_t^* = \left(\frac{\partial V^*}{\partial W_t} \right)^{\frac{-1}{\gamma}}$$

Optimal Value Function PDE

Now substitute π_t^* and c_t^* in $\Phi(t, W_t; \pi_t, c_t)$ and equate to $\rho V^*(t, W_t)$, which gets us the Optimal Value Function PDE:

$$\frac{\partial V^*}{\partial t} - \frac{(\mu - r)^2}{2\sigma^2} \cdot \frac{(\frac{\partial V^*}{\partial W_t})^2}{\frac{\partial^2 V^*}{\partial W_t^2}} + \frac{\partial V^*}{\partial W_t} \cdot r \cdot W_t + \frac{\gamma}{1 - \gamma} \cdot \left(\frac{\partial V^*}{\partial W_t}\right)^{\frac{\gamma-1}{\gamma}} = \rho V^*$$

The boundary condition is:

$$V^*(T, W_T) = \epsilon^\gamma \cdot \frac{W_T^{1-\gamma}}{1 - \gamma}$$

The second-order conditions for Φ are satisfied **under the assumptions** $c_t^* > 0$, $W_t > 0$, $\frac{\partial^2 V^*}{\partial W_t^2} < 0$ for all $0 \leq t < T$ (we will later show that these are all satisfied in the solution we derive), and for concave $U(\cdot)$, i.e., $\gamma > 0$

Solving the PDE with a guess solution

We surmise with a guess solution

$$V^*(t, W_t) = f(t)^\gamma \cdot \frac{W_t^{1-\gamma}}{1-\gamma}$$

Then,

$$\frac{\partial V^*}{\partial t} = \gamma \cdot f(t)^{\gamma-1} \cdot f'(t) \cdot \frac{W_t^{1-\gamma}}{1-\gamma}$$

$$\frac{\partial V^*}{\partial W_t} = f(t)^\gamma \cdot W_t^{-\gamma}$$

$$\frac{\partial^2 V^*}{\partial W_t^2} = -f(t)^\gamma \cdot \gamma \cdot W_t^{-\gamma-1}$$

PDE reduced to an ODE

Substituting the guess solution in the PDE, we get the simple ODE:

$$f'(t) = \nu \cdot f(t) - 1$$

where

$$\nu = \frac{\rho - (1 - \gamma) \cdot \left(\frac{(\mu - r)^2}{2\sigma^2\gamma} + r \right)}{\gamma}$$

with boundary condition $f(T) = \epsilon$.

The solution to this ODE is:

$$f(t) = \begin{cases} \frac{1 + (\nu\epsilon - 1) \cdot e^{-\nu(T-t)}}{\nu} & \text{for } \nu \neq 0 \\ T - t + \epsilon & \text{for } \nu = 0 \end{cases}$$

Optimal Allocation and Consumption

Putting it all together (substituting the solution for $f(t)$), we get:

$$\pi^*(t, W_t) = \frac{\mu - r}{\sigma^2 \gamma}$$

$$c^*(t, W_t) = \frac{W_t}{f(t)} = \begin{cases} \frac{\nu \cdot W_t}{1 + (\nu \epsilon - 1) \cdot e^{-\nu(T-t)}} & \text{for } \nu \neq 0 \\ \frac{W_t}{T-t+\epsilon} & \text{for } \nu = 0 \end{cases}$$

$$V^*(t, W_t) = \begin{cases} \frac{(1 + (\nu \epsilon - 1) \cdot e^{-\nu(T-t)})^\gamma}{\nu^\gamma} \cdot \frac{W_t^{1-\gamma}}{1-\gamma} & \text{for } \nu \neq 0 \\ \frac{(T-t+\epsilon)^\gamma \cdot W_t^{1-\gamma}}{1-\gamma} & \text{for } \nu = 0 \end{cases}$$

- $f(t) > 0$ for all $0 \leq t < T$ (for all ν) ensures $W_t, c_t^* > 0$, $\frac{\partial^2 V^*}{\partial W_t^2} < 0$. This ensures the constraints $W_t > 0$ and $c_t \geq 0$ are satisfied and the second-order conditions for Φ are also satisfied.
- The HJB Formulation was key and this solution approach provides a template for similar continuous-time stochastic control problems.

Gaining Insights into the Solution

- Optimal Allocation $\pi^*(t, W_t)$ is constant (independent of t and W_t)
- Optimal Fractional Consumption $\frac{c^*(t, W_t)}{W_t}$ depends only on t ($= \frac{1}{f(t)}$)
- With Optimal Allocation & Consumption, the Wealth process is:

$$\frac{dW_t}{W_t} = \left(r + \frac{(\mu - r)^2}{\sigma^2 \gamma} - \frac{1}{f(t)} \right) \cdot dt + \frac{\mu - r}{\sigma \gamma} \cdot dz_t$$

- Expected Portfolio Return is constant over time ($= r + \frac{(\mu - r)^2}{\sigma^2 \gamma}$)
- Assuming $\epsilon < \frac{1}{\nu}$, Fractional Consumption $\frac{1}{f(t)}$ increases over time
- Expected Rate of Wealth Growth $r + \frac{(\mu - r)^2}{\sigma^2 \gamma} - \frac{1}{f(t)}$ decreases over time
- If $r + \frac{(\mu - r)^2}{\sigma^2 \gamma} > \frac{1}{f(0)}$, we start by Consuming $<$ Expected Portfolio Growth and over time, we Consume $>$ Expected Portfolio Growth
- Wealth Growth Volatility is constant ($= \frac{\mu - r}{\sigma \gamma}$)

Fractional Consumption and Expected Wealth Growth

Time-Trajectory of Expected Wealth

Gaining Insights into the Solution

- Optimal Allocation $\pi^*(t, W_t)$ is constant (independent of t and W_t)
- Optimal Fractional Consumption $\frac{c^*(t, W_t)}{W_t}$ depends only on t ($= \frac{1}{f(t)}$)
- With Optimal Allocation & Consumption, the Wealth process is:

$$\frac{dW_t}{W_t} = \left(r + \frac{(\mu - r)^2}{\sigma^2 \gamma} - \frac{1}{f(t)} \right) \cdot dt + \frac{\mu - r}{\sigma \gamma} \cdot dz_t$$

- Expected Portfolio Return is constant over time ($= r + \frac{(\mu - r)^2}{\sigma^2 \gamma}$)
- Assuming $\epsilon < \frac{1}{\nu}$, Fractional Consumption $\frac{1}{f(t)}$ increases over time
- Expected Rate of Wealth Growth $r + \frac{(\mu - r)^2}{\sigma^2 \gamma} - \frac{1}{f(t)}$ decreases over time
- If $r + \frac{(\mu - r)^2}{\sigma^2 \gamma} > \frac{1}{f(0)}$, we start by Consuming $<$ Expected Portfolio Growth and over time, we Consume $>$ Expected Portfolio Growth
- Wealth Growth Volatility is constant ($= \frac{\mu - r}{\sigma \gamma}$)

- Analytical tractability in Merton's formulation was due to:
 - Normal distribution of asset returns
 - Constant Relative Risk-Aversion
 - Frictionless, continuous trading
- However, real-world situation involves:
 - Discrete amounts of assets to hold and discrete quantities of trades
 - Transaction costs
 - Locked-out days for trading
 - Non-stationary/arbitrary/correlated processes of multiple assets
 - Changing/uncertain risk-free rate
 - Consumption constraints
 - Arbitrary Risk-Aversion/Utility specification
- \Rightarrow Approximate Dynamic Programming or Reinforcement Learning
- Large Action Space points to Policy Gradient Algorithms
